

# The Legitimate Vulnerability Market: The Secretive World of 0-Day Exploit Sales

*Charles Miller*

*Principal Security Analyst*

*Independent Security Evaluators*

*June 7, 2007*

*[cmiller@securityevaluators.com](mailto:cmiller@securityevaluators.com)*

# Agenda

- Introduction
- Obstacles faced by researchers
- Potential solutions
- Case studies
- Implications to Internet security
- Conclusions

# Why am I here

- Question 1:
  - § iDefense Labs is offering \$16-24k for each vulnerability found in applications such as Apache httpd, OpenSSH, Sendmail, IIS
  - § Is this a good deal for researchers?
- Question 2:
  - § In 2006, the U.S. Department of Homeland Security gave \$1.24 million to Stanford and Coverity to hunt bugs in open source software
  - § Is this the best use of money to find vulnerabilities?
- What do the answers to these questions mean for Internet security in general?

# Introduction

- Vulnerabilities have been bought and sold for many years
- A few programs exist which pay researchers for vulnerability information:
  - § Zero Day Initiative (TippingPoint)
  - § Vulnerability Contributor Program (iDefense)
  - § Exploit Acquisition Program (SNOsoft)
- Some companies sell tools or packages containing 0-day exploits
  - § Ultimate 0day Exploits Pack (Argeniss)
  - § VulnDisco Pack (GLEG)
  - § Canvas (IMMUNITY)
- How can a researcher get paid a fair value in the legal vulnerability market?

# Obstacles faced

# Time sensitivity

- Vulnerability information is only valuable when it is not widely known
- A patch can make it worthless
- Other technologies, SELinux, /GS flag, other patches, newer versions can reduce the value
- Researcher doesn't have knowledge of when these things will occur (except "Patch Tuesday")
- Therefore, researchers must be able to locate a buyer and complete a sale quickly

# No pricing transparency

Vulnerability/Exploit	Value	Source
"Some exploits"	\$200,000 - \$250,000	A government official referring to what "some people" pay
a "real good" exploit	over \$100,000	Official from SNOsoft research team
Vista exploit	\$50,000	Raimund Genes, Trend Micro
"Weaponized exploit"	\$20,000-\$30,000	David Maynor, SecureWorks
ZDI, iDefense purchases	\$2,000-\$10,000	David Maynor, SecureWorks
WMF exploit	\$4000	Alexander Gostev, Kaspersky
Microsoft Excel	> \$1200	Ebay auction site
Mozilla	\$500	Mozilla bug bounty program

# Difficulty finding buyers

- No public marketplace
- Must contact many potential buyers
- Companies do not advertise that they buy vulnerabilities
- Good luck contacting the government
- Perhaps vendors should buy this information...

# Checking the buyer

- How does the researcher verify that a buyer is legitimate, i.e. not a terrorist or criminal?
- Need trusted third parties

# Value cannot be demonstrated without loss

- Once the vulnerability is shown to a potential buyer, why should they pay for it?
- Demonstrating via exploit is no better
- Giving too much vague information can reveal the vulnerability
  - § Version
  - § Authentication
  - § Stability
- Typically, buyers require seeing the exploit/vulnerability information before they send payment (or even make an offer)

# Exclusivity

- How does the researcher guarantee exclusivity of rights?
- “Sometimes we get burnt, sometimes not”  
- Dave Aitel

# Solutions

# Small steps

- Post a hash of the exploit
- “Mutually assured destruction”
- Proving the exploit exists
  - § can be done in person

# Market place solutions

- Of the 5 market types suggested by Bohme in “Vulnerability Markets”, only one
  - § Doesn't require vendor initiation and
  - § Has immediate incentive for researcher
- Exploit derivatives
  - § Contracts which pay based on whether vulnerability events occur
  - § Researchers benefit with “insider” knowledge
  - § Advantage: no exploits need to actually be sold.
  - § Disadvantage: unclear how much researchers could make.
  - § Requires a TTP

# Direct auction

- Sell exploit to the highest bidder(s)
- Has been tried via Ebay
- Could use “reputational” system
- Could offer escrow services
- Visibility into pricing and vulnerability information is obtained
- Drawbacks: legality, exclusivity

# Case studies

# Case Study #1 - Samba

- Summer of 2005, I discovered a remote vulnerability in Samba - a common Linux server:

```
static BOOL lsa_io_trans_names(const char *desc, LSA_TRANS_NAME_ENUM2 *trn, prs_struct *ps, int
depth)
{
...
    if(!prs_uint32("num_entries    ", ps, depth, &trn->num_entries))
...
    if (trn->ptr_trans_names != 0) {
        if(!prs_uint32("num_entries2    ", ps, depth, &trn->num_entries2))
            return False;
...
        if (UNMARSHALLING(ps)) {
            if ((trn->name = PRS_ALLOC_MEM(ps, LSA_TRANS_NAME2, trn->num_entries)) ==
NULL) {
                return False;
...
            }
...
            for (i = 0; i < trn->num_entries2; i++) {
...
                if(!lsa_io_trans_name2(t, &trn->name[i], ps, depth))
```

[Full-disclosure] Security researcher

**From:** asdfasf (*zerodayinithotmail.com*)  
**Date:** Fri Aug 25 2006 - 09:01:39 CDT

**Messages sorted by:** [\[ date \]](#) [\[ thread \]](#) [\[ subject \]](#) [\[ author \]](#)

I'm looking for a security researcher named "Gobbles". If anyone could send me his contact information I would appreciate it.

# Summary of Bug #1

- Due to no centralized place of contact, information sat for 5 months
- The government is slow....
- Had no idea of a fair market value
- Forced to give 10% to broker
- Only found broker due to personal contacts
- Sale helped by personal contacts
- Exploit given before any payment or signed contract
- *Sale occurred despite the market*

# Case Study #2: Powerpoint

- Approached by friend to help him sell a 0-day Microsoft Powerpoint vulnerability
- This time, not so lucky

Microsoft®  
**PowerPoint®**  
**2000**   
MICROSOFT OFFICE

# Value

- I felt it was worth \$20k
- I received offers as low as \$5k
- I negotiated with a company from \$8k up to \$12k

# Summary of Bug #2

- Lack of transparency meant pricing was basically arbitrary
- Lack of speed finding a buyer ruined sale
  - § The negotiation with the final company went quickly but started too late
- Sale could not proceed without shared personal contacts
- Exploit was to be sent before payment

# Implications to Internet Security

- Summarizing
  - § Researchers forced to act in secret
  - § Buyers that pay the most (by a factor of 10) for vulnerability information do not release it to the vendor
  - § Vendors do not pay researchers
- Therefore
  - § Researchers have an economic incentive not to inform vendor or anyone who will
  - § “Privileged” parties are aware of vulnerability information months or years ahead of the vendor - and public.
  - § Researchers not motivated to find vulnerabilities

# Conclusions

- Secrecy of market hurts security researchers
- Difficult to:
  - § Find a buyer
  - § Determine price
  - § Prove value of vulnerability/exploit
  - § Exchange goods for money
- No TTP leaves researchers vulnerable to losing their vulnerability information
- Time sensitivity compounds problems
- Some solutions exist but implementation remains far off
- Vulnerabilities **are** rediscovered!
- The implication of “high end” vulnerability sales is that the Internet is a less safe place - *vendors need to pay researchers!*
